Modeling the Long-Term Behavior of Structural Timber J Rg Sch Nzlin,Jörg Schänzlin,2011-02 Creep deformation influences the serviceability limit state as well as the ultimate limit state of timber structures In order to consider this time dependent behavior creep coefficients and rheological models have been developed by various researchers Comparing the rheological models quite different temporal deformations are evaluated for a duration of load of 50 years In order to find the model which is most suitable to the situation in the region of Tübingen South West Germany the existing deformations of several beams in roof structures in opened protected but not heated buildings are measured By loading the structure the elastic global stiffness of the particular element is determined So creep coefficients can be evaluated which should have been used by the engineer in order to get the existing deflection after 50 years Within the region of Tübingen on average a creep coefficient of 2.23 was found based on these measurements However the standard deviation of 0.97 is quite large For the numerical evaluation of the time dependent behavior Toratti's model is modified so that it matches the measured deformations
