

# Chapter 15: Continental Flood Basalts

The image shows a dramatic coastal landscape. In the foreground, a steep, rocky cliff face dominates the view. The cliff is characterized by prominent, horizontal, light-colored rock layers, which are likely flood basalts as mentioned in the chapter title. These layers are separated by darker, more irregular rock. The top of the cliff is a flat, grassy plateau. To the left, the cliff meets the sea, with some smaller rock formations visible in the water. The sky is filled with soft, white clouds, and the overall scene is captured in a slightly desaturated, naturalistic style.

Coffin, 1997-01-23 Published by the American Geophysical Union as part of the Geophysical Monograph Series Volume 100 Continental flood basalts volcanic passive margins and oceanic plateaus represent the largest known volcanic episodes on our planet yet they are not easily explained by plate tectonics Indeed some are likely to record periods when the outward transfer of material and energy from the Earth's interior operated in a significantly different mode than at present In recent years interest in large scale mafic magmatism has surged as high precision geochronological detailed geochemical and increasingly sophisticated geophysical data have become available for many provinces However the sheer amount of recent material often in the form of detailed collaborative research projects can overwhelm newcomers to the field and experts alike as the literature continues to grow dramatically The need for an up to date review volume on a sizable subset of the major continental and oceanic flood basalt provinces termed large igneous provinces was recognized by the Commission on Large Volume Basaltic Provinces International Association of Volcanology and Chemistry of the Earth's Interior and the co editors were charged with organizing and implementing such a volume We hope that this volume will be valuable to researchers and graduate students worldwide particularly to petrologists geochemists geochronologists geodynamicists and plate tectonics specialists it may also interest planetologists oceanographers and atmospheric scientists      **Extensive**

*Enriched Mantle Component(s) in Proterozoic Continental Flood Basalts of the Cape Smith Foldbelt, Northern Quebec* Sheldon Modeland, 2001 The Cape Smith foldbelt is one of Earth's best exposed Proterozoic mobile belts and provides a natural laboratory for the study of Proterozoic mafic magmatism. Magmatism associated with circa 2.04 Ga rifting of the Superior Province resulted in the formation of tholeiitic and alkaline basalts as well as minor rhyolites collectively known as the Povungnituk Group. Despite their continental setting the tholeiites are not typical continental flood basalts in that they lack significant negative Nb and Ta anomalies relative to light rare earth elements and primitive mantle thus indicating that crustal contamination did not play a major role in their evolution. Although crystal fractionation along a gabbroic cotectic can account for much of the variation in trace element concentrations this process cannot explain the wide range of observed incompatible trace element ratios within the Povungnituk Group. Despite their continental setting the Povungnituk Group lavas exhibit a range of incompatible trace element contents similar to that from tholeiitic to highly alkaline lavas in modern ocean island basalt suites such as Hawaii the dominant relatively depleted lavas of the Povungnituk Group are most similar to the basalts of oceanic plateau suites and the upper lava flows of some continental flood basalt suites.
