**Semi-analytic Approach to Analyze Single Well Tracer Tests TR-44** ,1984 Residual oil saturation is one of the most important parameters to be considered when analyzing a prospective field for enhanced oil recovery Traditionally residual oil saturation has been estimated from cores or well logs These methods have a small radius of investigation evaluating saturations in a region close to the wellbore This region is often affected by injection or production operations Single well tracer tests have proven to be a better alternative to estimate residual oil saturation since they cover a substantially larger volume of the reservoir and thus measure a more representative residual oil saturation of the target formation The method consists of the injection of a reactive tracer that is soluble in oil and water This tracer slowly hydrolyzes forming a secondary tracer as a product of an irreversible chemical reaction After injection the well is shut in to allow the formation of a detectable amount of secondary tracer which is soluble only in water When the well is open to production each tracer arrives to the well at different times From the separation between the concentration peaks residual oil saturation is estimated However the determination of the residual oil saturation through the analysis of single well tracer test production data in the past has required 1 the use of finite difference simulators 2 five fitting parameters and 3 considerable man computer interaction time In addition finite difference simulators give results that are affected by numerical dispersion This and the fitting parameters add uncertainty to the uniqueness of the solution In this work a new approach is presented The test is analyzed 28 references 70 figures 7 tables
