An Improved Apparatus for the Determination of Gaseous Elements in Metals by Vacuum Fusion on a Micro Scale

By J. N. GREGORY AND D. MAPPER

This paper describes some improvements to a vacuum fusion apparatus previously described by the same authors in this journal.

The improvements relate mainly to more efficient pumping and recovery of the evolved gases, and the introduction of a low-pressure method of gas analysis.

The latter has enabled the complete results on a series of samples to be obtained in about half a day, compared with 2 or 3 days by the previous method.

In a recent paper,¹ we described an apparatus which has been used for the determination of gaseous elements in uranium and steel on a micro scale, at the 10 to 100 p.p.m. level. In an apparatus of this type it is essential to pump the evolved gases away from the high-temperature region as rapidly as possible. It is also necessary to confine the metal and its vapour as much as possible to the region of maximum temperature in the crucible. If these two requirements are not adequately met, losses will occur owing to reaction of the evolved gases with metal deposited on the lower-temperature regions of the crucible and heat shield.

It was found that the pumping rate and the method of confinement of the metal sample to the crucible in the apparatus previously described were not adequate in the case of beryllium, which has a very high vapour pressure at the temperatures required to decompose the oxide. Very high pumping rates are needed with careful confinement of the metal to the crucible to avoid large recombination losses and massive evaporation of the metal to the walls of the silica jacket.

The modifications described in this paper were specifically designed to make the apparatus more efficient for the determination of gases in beryllium, but they will also give more efficient determination of gases in other metals.
